

As the world shifts towards more sustainable energy sources, understanding the chemistry behind wind energy becomes increasingly important. This article delves into the ...

Most of the wind turbines contain SF6 gas, which is 23,500 times more potent greenhouse gas than carbon dioxide and remains in the atmosphere for at least 1,000 years. Sulphur hexafluoride, or SF6, ...

Through a system of sensors and pressure valves, the generator can supply the wind turbines with on-demand nitrogen, greatly reducing the chances that the gas and fluid sides of the ...

Wind turbines generate no energy when the wind doesn't blow, and there is no gas generator inside. Wheel energy also lacks the versatility of natural gas and oil, with a carbon footprint ...

Power plants that burn natural gas are responsible for 437 to 758 grams of CO2-equivalent per kilowatt-hour -- far more than even the most carbon-intensive wind turbine listed above.

Wind turbines work on a simple principle: instead of using electricity to make wind--like a fan--wind turbines use wind to make electricity. Wind turns the propeller-like blades of a turbine around a rotor, ...

More specifically, they figure that wind turbines average just 11 ...

Sulphur hexafluoride, or SF6 for short, is indeed a climate-damaging gas. Just one kilogram of it is as harmful as about 23,000 kilograms of carbon dioxide. "This climate killer is almost always found in ...

More specifically, they figure that wind turbines average just 11 grams of CO2 emission per kilowatthour of electricity generated. That compares with 44 g/kwh for solar, 450 g for natural...

Sulfur hexafluoride (SF6) is a synthetic gas used in the manufacture of wind turbines as an interrupter and an insulator. There is also one very potent greenhouse gas which contribute to climate change ...

For example, Colorado-based Hybrid Turbines Inc. is selling wind farms systems that marry a natural gas-based generator to a wind turbine. "Even if natural gas is used, the electricity ...
